III RENware support

I. System overview

ALPHAREN CORE-Integrator (ARINT) System

(c) 2021 RENware Software Systems. RESTRICTED only for project internal use

1 ALPHAREN CORE-Integrator

- [ALPHAREN CORE-Integrator](#)
 - [Product information](#)
 - [Documentation](#)
 - [Demo system](#)
 - [Support and assistance](#)

1.1 Product information

- p/n code: 0000-6151
- product short name: arint
- product version: 0.1
- product page: <http://arint.renware.eu> (<http://arint.renware.eu>)
- initial start: 2021

This product (as a "whole") is manufactured, registered and licensed by [RENware Software Systems](http://www.renware.eu) (<http://www.renware.eu>) which is the copyright holder. On the other hand product components / spare parts are under producers copyright ([here can be found detail about components](#)).

1.2 Documentation

Product documentation is divided in:

- **Overview** contains the information to understand your **ARINT** system and start of using it
- **User help** which represents a set of procedures for "day by day" operations
- **System administration** which contains in essence necessary information to install, configure and maintain the system

To access documentation just follow the navigation entries.

1.3 Demo system

The system site contains also a link to a demo system where you can see & try the system "at work" and try its capabilities.

Demo system entered data

Pay attention that this system is just a demo and no saved data is guaranteed to be preserved even your information is stored under your "user context". Keep in mind that's just a demonstration system and **do not store sensitive data**.

1.4 Support and assistance

The product site give you information about how to access support channel and how to buy this product. Support channel is offered from producer site but depending on your country this will redirect you to most appropriate local dealer.

ALPHAREN CORE-Integrator (ARINT) System

(c) 2021 RENware Software Systems. RESTRICTED only for project internal use

2 Core-Integrator System Overview

Table of contents:

- [Core-Integrator System Overview](#)
 - [What is ARINT Core](#)
 - [Availability and system "presence"](#)
 - [Features](#)
 - [Typical use cases](#)

2.1 What is ARINT Core

ALPHAREN Core Integrator (aka **ARINT** or **arint**) system is a framework product for automation, integration and interoperability between *distributed systems* or *data sources* basically aimed to build *API oriented, middleware, frontend* and *backend* applications.

Practically it allows to create small-footprint and focused *business oriented microservices* or to transform "monolith" applications to micro-applications that will act as *a single one* but with a high degree of *maintainability*.

Product is available as *distinct software* or as *ready to run appliance* (including also some built-in components such as an internal database for business operations).

ARINT as Service bus

ARINT acts as a high level *Service BUS* (ie, ESB or ESOA) to connect different micro-services and to make them to work **as one**. As example it is already used by all *RENware Software Systems* products. Of course it can be used for **CUSTOMER SYSTEMS and SERVICES** too.

ARINT generic process flow is:

i Remarks to diagram

- practically an **IN channel** establish a way to address the ARINT system, how to call it
- a **Repetitive Service** is normally called once (ie, to start it) and it begins to repeat operations (in background) at *defined time intervals* and for a *defined period* (or indefinitely)

2.2 Availability and system "presence"

- **ANYWHERE.** can work even the systems that must be integrated are in different non routable LANs (address systems at **http** protocol level)
- **ANYHOW.** is agnostic to format, composition, structure, encoding of information required / provided by systems that must be integrated
- **ANYTIME.** can work as a distributed high scalable cluster of "**ALPHA-REN Integrator Machines**"

- **SECURED.** can work with any public standard (ie, defined at least as **RFC**) of Internet security

Each ARINT system (cluster containing one or more servers) can run on premises or in cloud deployed as classic software or Docker application container, Kubernetes node / container or as any general containerization "standard" method.

2.3 Features

For [features list go here](#)

2.4 Typical use cases

ALPHAREN CORE-Integrator is used for enterprise, business integrations, data science, IoT and other scenarios that require integrations of multiple systems.

Real-world, production **ALPHAREN CORE-Integrator** environments include:

- A platform for processing payments from consumer devices
- A system for a telecom operators integrating CRM, ERP, Billing and other systems as well as applications of the operator's external partners
- A data science system for processing of information related to securities transactions (FIX)
- A platform for public administration systems, helping achieve healthcare data interoperability through the integration of independent data sources, databases and health information exchanges (HIE)
- A global IoT platform integrating medical devices
- A platform to process events produced by early warning systems, (ex SAP EWS)
- Backend e-commerce systems managing multiple suppliers, marketplaces and process flows B2B platforms to accept and process multi-channel orders in cooperation with backend ERP and CRM systems
- Platforms integrating real-estate applications, collecting data from independent data sources to present unified APIs to internal and external applications
- A system for the management of hardware resources of an enterprise cloud provider
- Online auction sites
- E-learning platforms
- Ad-hoc data API for databases for example to protect them to direct access or to hide particular implementation details (especially in legacy old databases) allowing for a smooth and transparent transition to new redesigned implementations

ALPHAREN CORE-Integrator (ARINT) System

(c) 2021 RENware Software Systems. RESTRICTED only for project internal use

3 Product features

Table of contents:

- [Product features](#)
 - [General features](#)
 - [Standards compliance](#)
 - [Services level issues and features](#)
 - [Frequent service type examples](#)
 - [ARINT own objects and components](#)
-

3.1 General features

- Open API full compliant
- Integrations, Microservices, SOA and ESB in Python
- HA load-balancer, hot-deployment and hot-reconfiguration - deploy with no downtime Browser-based GUI, CLI and
- API - easy to use and customize

For an [overview of the product please see](#).

3.2 Standards compliance

The following list presents the most known standards, protocols, data stores, formats, and so on, *that ARINT system can use and is compliant with*.

The actual list is larger and practically *any kind of specific interface* can be written in services as long as is written the corresponding code.

Standards update

Also verify your system version and update it as new standards can be included in official package releases.

The order of items is not relevant (meaning that it does not pursue a specific objective). Also classification made is not *an exact one* as some items can be categorized in more places. If someone know exactly what standard is looking for, a traversal of the entire list is best option.

- Protocols:
 - REST
 - SOAP
 - FTP
 - SFTP
 - LDAP
 - Active Directory
 - WebSockets
- Industry standards:
 - HL7 (healthcare - data exchange)
 - RBAC (IT - Role Based Access Control)
 - Swift (banking - Society for Worldwide Interbank Financial Telecommunication)
- Business systems:
 - SAP
 - Odoo
- Mail and messaging protocol and systems:
 - SMTP
 - IMAP
 - Telegram
 - JMS
 - Twilio
 - Slack
- Data languages and formats;
 - OpenAPI
 - SQL
- Databases and broker systems:
 - MongoDB
 - Redis
 - Memcached
 - Cassandra
 - Kafka

- Search systems:
 - ElasticSearch
 - Solr (Apache)
- File oriented stores and depots:
 - Amazon S3
- Queue based communication systems:
 - AMQP
 - IBM MQ
 - ZeroMQ
 - JMS (Java Message Service)
- Security and protection:
 - Vault
 - all cryptography standard algorithms

3.3 Services level issues and features

In writing an ARINT services there are some frequent and repeating issues. An ARINT service address them by offering built-in solutions and ***let developer focus on business aspects***. Addressed issues are:

- How do I connect to ARINT own resources ? How do I send user entered credentials to ARINT?
- How do I connect to external systems or databases to store or extract data?
- How do I convert and / or map messages from one format to another?
- How do I automate my work so that it is repeatable across environments (ie, environments like `development`, `test`, `production`)?
- How can I focus on my job instead of thinking of trivial low-level details?
- How do I debug my code?
- How can I reuse the skills and knowledge that I obtained elsewhere and how can I better myself?
- How do I manage the complexity of having to integrate at least several systems and dozens or hundreds of APIs?

All these questions have answers in "Development documentation", [Development Overview being a good start](#).

3.4 Frequent service type examples

Here are some examples of what kind of services can be accomplished by ARINT:

**Most popular**

Technologies most commonly used in API integrations: *REST | SOAP | Scheduler | Pub/sub | SFTP | WebSockets*

**Databases and message queues**

How to access commonly used data sources: *SQL | MongoDB | Redis | AMQP | IBM MQ | ElasticSearch*

**Business apps**

Integrating with 3rd party CRM and ERP software: *Microsoft 365 | Salesforce | Odoo*

**Health care interoperability**

Integrating health systems meaningfully: *HL7 FHIR | Security*

**E-mail**

How to send and receive emails: *IMAP | SMTP | Microsoft 365*

**Shell commands**

Turning shell commands into API services: *Shell commands | SSH | PowerShell*

**File integrations**

Integrating systems using continuous or batch file transfer: *File transfer | SFTP | FTP*

**Requests, responses and data models**

Convenient access to request and response data: *Requests | Responses | Data models | OpenAPI*

**Cloud integrations**

Integrating with popular cloud providers: *AWS S3 | Jira | Confluence | WordPress*

**LDAP and OAuth**

Integrating with external security providers: *LDAP and Active Directory* / *OAuth and REST*

These are only some kind of type of supplementary services that can be written in ARINT. More details about services will be found in [Development - Service anatomy](#).

3.5 ARINT own objects and components

Besides the features offered as external systems integration, the ARINT has its internal objects and components (that will be detailed in other documents). These are:

- **System database** containing all ARINT meta-information about its objects
- **Business database** containing all business entities and objects with their effective data
- **Master data** containing all "cross instances" master data objects (more exactly master data objects that are agnostic to business entities and objects content)

A [detailed description of System Data & Objects](#).

ALPHAREN CORE-Integrator (ARINT) System

(c) 2021 RENware Software Systems. RESTRICTED only for project internal use

4 System Landscape

Document control:

* last update date: 230607

* last updated by: petre iordanescu

Table of contents:

- [System Landscape](#)
 - [Basic components](#)
 - [System Blueprints](#)
 - [ARint blueprint](#)
 - [ARCLST blueprint](#)
 - [ARCLST. Integrator Cluster](#)
 - [ARSRV. Integrator Server](#)
 - [ARLDB. Integrator High Availability assurance subsystem](#)
 - [ARWADM Web admin console](#)
 - [ARDPX. Access and distribution proxy](#)
 - [ARMAIL Integrator mail](#)
 - [ARVPN. Integrator VPN access](#)
 - [Deployment over multiple LAN environments](#)

4.1 Basic components

Basic logical components of this system are:

- **(ARCLST)** Integrator Cluster subsystem
 - **(ARSRV)** Physical or virtual Server
 - **(ARLDB)** High Availability assurance service
 - **(ARWADM)** Web admin console interface
 - **(ARSCHED)** Scheduler
 - **(ARKVD)** Key-Value Data store

- **(ARPuSuB)** Publisher Subscriber Queues
- **(ARVPN)** Integrator VPN access
- **(ARDPX)** Discovery Service, Distribution proxy (dynamic DNS)
- **(ARMAIL)** Integrator mail
- **(#TODO)** Configuration portal #NOTE: not yet assigned code

4.2 System Blueprints

4.2.1 ARint blueprint

-#TODO a high level blueprint

4.2.2 ARCLST blueprint

-#TODO start and make new descriptions (based on existing) for each component

-#TODO - from here continue review

4.3 ARCLST. Integrator Cluster

This component creates a local cluster formed by one or more **ARSRV** machines. Particularly can stand on one single machine with **ARSRV**.

This is not recommended because **ARCLST** is a *network-bounded* system and **ARSRV** is a *cpu-bounded* one, and a *cluster to cluster* integration will have to suffer.

This component can run **1 per LAN machine**.

4.4 ARSRV. Integrator Server

This is the core / heart of each machine. It will assure information getting, processing and sending or streing.

Other functionalities (in cooperation with **ARCLST**) cover scheduling, asynchronous processing and retrying in case of un-availability of an external system.

This component can run **n per cluster**.

4.5 ARLDB. Integrator High Availability assurance subsystem

This component assure:

- load balancing,
- failure detection,
- service availability,
- RTT ordering access to in case of multiple **ARSRV** modules.

All **ARSRV** components work *ACTIVE ACTIVE* inside any **ARCLST**. Of course, clusters work independently each of the others.

Also, each **ARLDB** keeps a dynamic trace of any **ARCLST** from the system, so a new cluster can be added without the need of any downtime.

This thing is also applicable inside a cluster where at any time, with any downtime, a new **ARSRV** can be added. If is right configured then will be automatically discovered and made part of cluster.

This component can run **1 per cluster**.

4.6 ARWADM Web amin console

This will assure cluster administration, for all its servers and other components.

This component can run **n per cluster**. The reason for more ARWADM is to secure each of them.

4.7 ARDPX. Access and distribution proxy

This module is useful when an **ARCLST** is built on **ARSRVs** physically implemented as a set of small virtual machines on a single server, having their LAN. Sure, ALPHA-REN hardware will assure that, but if you're using other hardware it will be needed.

This module will stay in own LAN DMZ being directly exposed on **ARCLST** IP external access.

This module is responsible for:

- access the system outside its LAN without the need of a router with port forwarding.
- assurance of all reverse proxy operations.
- access on the **ARCLST** and **ARSRVs** outside cluster LAN.

This component can run **1 per machine**.

4.8 ARMAIL Integrator mail

This module is responsible for sending administrative and notification mails from **ARCLST** cluster.

This component can run **1 per machine**.

4.9 ARVPN. Integrator VPN access

This module assure VPN access into the **ARCLST** cluster.

4.10 Deployment over multiple LAN environments

In an environment with multiple LANs, in deployment architecture and process should consider the following aspects:

- every LAN should have at least its own **ARSRV** in order to communicate with other LANs
- an **ARCLST** can assure balancing and failure services inside LAN
- in order to assure balancing and failure services over LANs, each one must have its own **ARCLST** (with all other required components to assure corresponding services) which communicate with the others.
- a queue service is strictly required both to assure messages transport inside LAN, but also between LANs; for this reason cannot be used any queuing system but one with remote (over LANs) capabilities (aka named broker system)

10 System Installation

Document control:

* last update date: 230605

* last updated by: petre iordanescu

Table of contents:

- [System Installation](#)
 - [Install helpers](#)
 - [Package key](#)
 - [Add apt repository](#)
 - [Install zato](#)
 - [Apply latest updates](#)
 - [Check & confirm](#)
 - [Create a quick cluster environment](#)
 - [Create the cluster](#)
 - [Change web console password](#)
 - [Configuration & access](#)
 - [Machine general configuration](#)
 - [Machine environment configuration](#)
 - [System launch scripts](#)
 - [Installation notes](#)

10.1 Install helpers

```
sudo apt-get install apt-transport-https curl
sudo apt-get install software-properties-common
sudo add-apt-repository universe
sudo apt-get install tzdata
```

10.1.1 Package key

```
curl -s https://zato.io/repo/zato-3.2-48849AAD40BCBB0E.pgp.txt | sudo apt-key add -
```

10.1.2 Add apt repository

```
sudo add-apt-repository \
    "deb [arch=amd64] https://zato.io/repo/stable/3.2/ubuntu $(lsb_release -cs) main"
```

10.1.3 Install zato

```
sudo apt-get install zato
```

10.1.4 Apply latest updates

```
sudo su - zato
cd /opt/zato/current && ./update.sh
```

10.1.5 Check & confirm

```
zato --version
```

10.2 Create a quick cluster environment

10.2.1 Create the cluster

This will create a new cluster ARCLST named **arclst** in directory `/opt/zato/env/arclst`.

```
sudo su - zato
mkdir -p ~/env/arclst
cd ~/env/arclst
zato quickstart create . sqlite localhost 6379
```

Response should looks like that:

```
[1/8] Certificate authority created
[2/8] ODB schema created
[3/8] ODB initial data created
[4/8] server1 created
[5/8] Load-balancer created
Superuser created successfully.
[6/8] Dashboard created
[7/8] Scheduler created
[8/8] Management scripts created
Quickstart cluster quickstart-904765 created
Dashboard user:[admin], password:[F7qC0iabas5ToQ7EWupLrH0n9iVHzyBv]
Visit https://zato.io/support for more information and support options
```

10.2.2 Change web console password

The username web administration console is **admin**. To change the password in **admin**, do:

```
cd ~/env/arclst/web-admin/  
zato update password . admin
```

10.3 Configuration & access

10.3.1 Machine general configuration

- Test machine ren-cluster, 192.168.1.190
- Admin console port 8183
- Credentials admin / admin
- public access http://90.84.237.32:8183 user admin pswd admin

10.3.2 Machine environment configuration

- User `sudo su - zato`
- Path `/opt/env/arclst`
- web admin console path `/opt/env/arclst/web-admin`
- ZATO Server `arclst`

10.3.3 System launch scripts

- `zato-qs-start.sh`
- `zato-qs-restart.sh`
- `zato-qs-stop.sh`

Server start in background mode, NOT as daemon.

10.4 Installation notes

None. Everything works as documented. ATTN open 8183 port

11 System Data and Objects

product version: 0.1

Table of contents:

- [System Data and Objects](#)
 - [Introductory](#)
 - [Naming rules](#)
 - [Object categories and models](#)
 - [Namespaces catalog](#)
 - [Namespace URRM](#)
 - [URRM catalog](#)
 - [URRM_new_object_x](#)
 - [Namespace ODEF](#)
 - [ODEF catalog](#)
 - [ODEF_new_object_x](#)
 - [Namespace MADA](#)
 - [MADA catalog](#)
 - [MADA_new_object_x](#)
 - [Notes and remarks](#)

11.1 Introductory

11.1.1 Naming rules

- Objects `code-name` is not case sensitive and is a good rule to use always uppercase. The system will convert the data objects `code-name` to uppercase, even from the save step.

- New "user or client or implementation" level business objects `code-name` should start with character `Z`. Any other ARINT objects do not use `Z` as first character in code-names, so this can make an *acceptable separation of those objects that are subject of change by system updates* and is a *guarantee that objects starting with `Z` in code-name will not be altered by any system update.*

11.1.2 Object categories and models

Any data object must be in one of these categories:

- **entity** - This is a relational data entity, more exactly a *table* to use the specific relational modeling concept. Such kind of objects are stored in relational system database.
- **json** - This is an object can contain any data model and type that respect `JSON` standard. This kind of object can cover almost all kind `NoSQL document type` variants. Such kind of object can be stored in any system database (relational or kv store) at your option. Default store place is kv system database.
- **crypto_key** - This kind of object contains keys used for cryptographic purposes. This kind of object is represented as a limited `json` type (strict one level, no arrays, only string type keys). A `crypto_key` object usually has one or two entries corresponding to one (in symmetrical cryptography) or two (in asymmetrical cryptography) keys, both as strings of `UTF-8` characters (bytes).
- **file** - This kind of object is designed to keep files or directories references. This references are stored can be stored in any system database (relational or kv store) and must respect all *Linux* conventions regarding file names (directories are files too represented as convention with a `/` character at end if is not obvious from context). So as a minimum strings of `UTF-8` characters (bytes) no more than 256 characters (bytes)

As definition models the `oo` definition is preferred and for relational objects the [SQLAlchemy](https://www.sqlalchemy.org/) (<https://www.sqlalchemy.org/>) is preferred option. For `kv` data the Python normal `dictionaries` can be used.

11.1.3 Namespaces catalog

Here are listed the main *area of objects* defined in *System database*. These are the equivalent of a `namespace` (or `schema` in relational databases terminology) and they will become in a way¹ a `prefix` for all entities / objects contained in.

- **URRM** user roles and rights management
- **ODEF** business objects definition
- **MADA** global master data (cross any systems, applications, nodes, ie global for an **ARINT instance**)
- -#NOTE future reserved ...

- **OBTYP** object types and models. This contains values described of ["Object types and models" section](#)
- -#NOTE future reserved ...

11.4.2 MADA_new_object_x

- -#NOTE future reserved ...

11.5 Notes and remarks

-
1. (PROPOSAL @ 230823 by piu): The way that concrete entities / objects are prefixed depends of database, ORM instrument used, etc. To keep as agnostic as possible this prefix will be used as *object name prefix* followed by `_` character. **All code-name s for a prefix will be kept in 4 characters.** [↩](#)

13 Development Overview

Table of contents:

- [Development Overview](#)
 - [Preliminaries](#)
 - [CHN - channel](#)
 - [SRV - service](#)
 - [File names](#)
 - [Services names](#)
-

13.1 Preliminaries

Development process over ARSRV implies basically the following components:

- **SRV** - service
- **CHN** - channel

Fundamentally and very high level, a service (SRV) use a channel (CHN) to communicate with external environment.

13.2 CHN - channel

A channel must be defined in **ARSRV** management interface before use. The channel can be:

- **IN channel** which establish and endpoint route through an ARINT service can be invoked (called)
- **OUT channel** which establish a "place whwere ARINT can write (send)" information

The CHN establish:

- an own name which uniquely identifies it
- the endpoint address
- the protocol used
- data formats in messages exchanged thru the channel
- auth and other security parameters

13.3 SRV - service

A service must be written in Python then deployed to **ARSRV** in order to be used.

A service has the following high level flow:

- defines a handler in order to be accessed by ARSRV
- obtain any required parameters in order to properly do its job
- connects to a channel to read required input
- make the necessary transformation over obtained data
- connects to a channel to write computed output
- log any process details for future references and errors debugging

13.4 File names

Development documents (except the current one) will be named as follows:

- **06.DEV** as prefix
- *optional* a code which specify (only if is case) at which subcomponent or pritocol, and so on
- name of the document

13.5 Services names

The producer reserve a name space for its services (as built in AR Integrator or as future updates) starting with characters **AR**.

The users are free to name how they wants their own developed services, but not start with AR characters. Respecting this rule will allow producer future updates to overwrite *client own developed services*.

This rule should apply as general validity for any components names, for example channel names.

*Anyway the customer must be aware that names starting with **AR** characters are reserved and are subject of future changes without any notice or change log.*

14 Service anatomy

Product 0000-0156 0.0 document control:

- 210728 me new doc
- 230817 me last update

Table of contents:

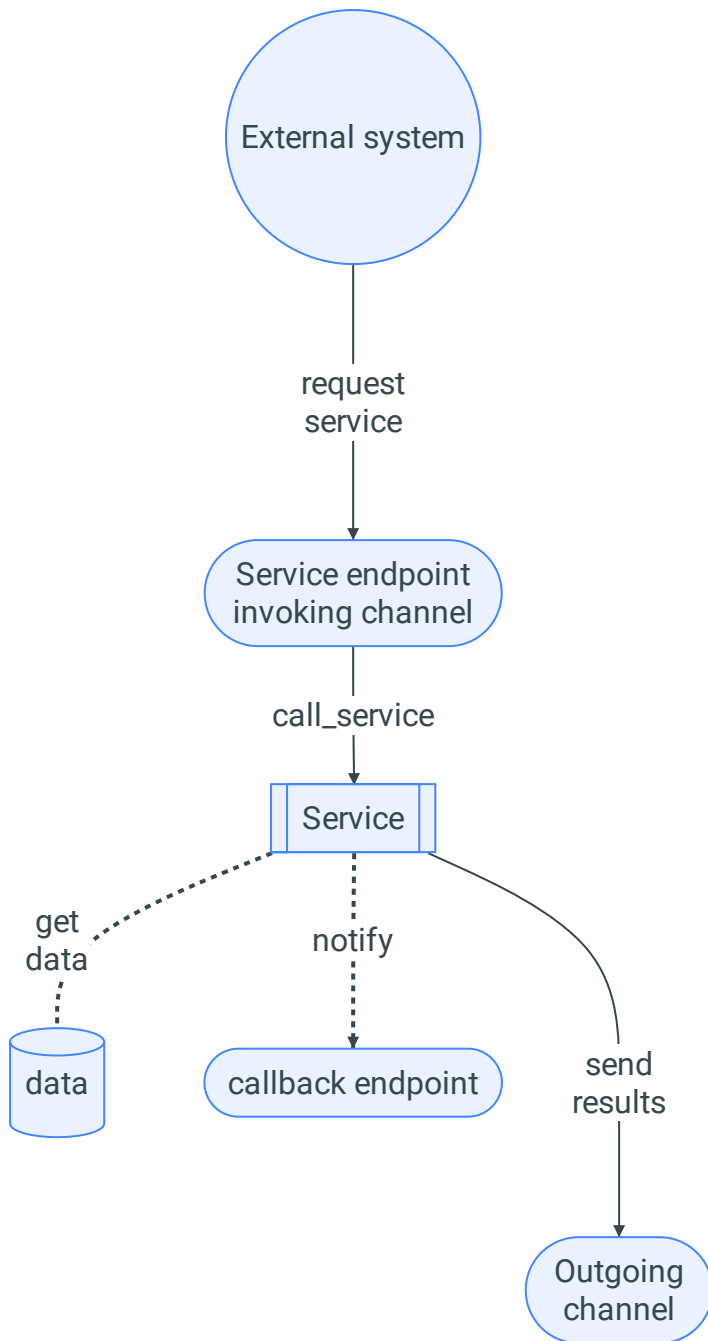

- [Service anatomy](#)
 - [Service skeleton](#)
 - [Detailed operations](#)
 - [Deployment](#)
 - [Using in real cases](#)

A service must be written in Python then deployed to **ARSRV** in order to be used.

14.1 Service skeleton

A service has the following high level flow:

- defines a handler in order to be accessed by ARSRV
- it is invoked through a channel
- obtain any required parameters in order to properly do its job
- connects to another channel to read required input, or directly read it, or obtain it from other service, etc (here we are in Python)
- make the necessary transformation over obtained data
- connects to an outgoing channel to write computed output
- log any process details for future references and errors debugging

14.1.1 Detailed operations

A service consists of a class which gives **its name**. This class must contain a method named `handler` each is called by ARSRV to execute the service.

```
# -*- coding: utf-8 -*-
# zato: ide-deploy=True

from zato.server.service import Service

class GetUserDetails(Service):
    """ Returns details of a user by the person's ID.
    """
    name = 'api.user.get-details'

    def handle(self):

        # For now, return static data only
        self.response.payload = {
            'user_name': 'John Doe',
            'user_type': 'SRT'
        }
```

The above example contains:

- first line is a comment for Python but will give important information to ARSRV ref service code serialization, useful to duplicate / copy the service on all servers (for load balancing and fail safe purposes).
- second line is a comment too but for Visual Code IDE add on to know that service should be automatically deployed at save.
- next is a Zato (part of ARSRV) library for right using services
- `self.response.payload` is the property where response must be returned from service processing; this property will be used by ARSRV as response of the service
- `name` will be the name of this service ad used by ARSRV
- the long comment (standard Python style for a multi line long string) will be used by ARSRV as service description

NOTE. The response format could be anything you want, but for a better serial, serialization and conversion to output channel format, IT IS RECOMMENDED TO USE A DICTIONARY for response payload.

14.2 Deployment

In order to deploy this service the following methods could be used:

- directly from IDE if the corresponding extension was installed - this depends by IDE platform - VS Code has an already written extension
- putting it in directory `~/env/qs-1/server1/pickup/incoming/services` and will be loaded automatically by an ARSRV, server1 shown in path (recommend for automate deployment)
- upload from ARSRV administration console (Services > List > Upload...)

In all cases the deployment ARSRV will distribute the service on all cluster's servers.

14.3 Using in real cases

In most cases will want to access this service by a request from other system. Therefore will be needed a channel (as endpoint) where to invoke the service and sending it data (pls remember that ***anything that is outside ARSRV is 'linked' to ARSRV thru channel***).

There could be cases when want that the service to run automatically driven by a scheduler. As long as ARSRV has its own scheduler, there is not need a channel to invoke the service.

And finally, the service can be invoked by other external event, like a new file in a directory, an updated file, a change in a database, a new message in a queue, a mail, etc. These aspects are ***subject to channels*** and will be treated there.

To produce an usable result, of course, the service must be linked to a channel which will receive response.

16 Basic concepts - in channels and calling a service

Table of contents:

- [Basic concepts - in channels and calling a service](#)
 - [In Channels overview](#)
 - [REST channel definition](#)
 - [Invoking the channel](#)

16.1 In Channels overview

An **IN channel** is a communication channel defined for *calling (invoking) a service* and act as *request endpoint* seen from outside world.

**Channel term**

The *IN channel* is also named simple *Channel* meaning that if no other details / hints are given, a "channel" should be understood as "IN channel".

Channels can use multiple standard protocols, such as: REST, AMQP, HL7, IBM MQ, JSON RPC, SOAP, Web Sockets, File Transfer protocols, and others.

A channel at request will invoke an existing service.

16.2 REST channel definition

For a *REST* channel, the following parameters must be provided:

- Name
- URL path
- Data format
- Service
- Security definition

Name is the ARCLST name of the channel.

URL path is the address of channel endpoint. This is part of ARCLST route, ie `ARCLST_path.../URL_path`.

Data format is the format of data that will be exchanged through this channel. Usual (for REST channels at least) is to specify here *JSON*.

Service is the name of the service that will be called when channel is invoked.

Security represents the security domain that will be applied to this channel.

Other parameters could also be specified here, for example if there are supplementary parameters (like those with ? after the route), header info (for out channels) and so on.

16.2.1 Invoking the channel

General form of invoking path will be: `http://<user>:<password>@ARCLST_path:11223/URL_path`.

The request is normally made thru load balancer (port 11223). The password is those defined at security domain definition.

NOTE: *The first slash (/) from URL path is part of was entered in definition and not is automatically appended. This will allow for combining channels.*

17 Outgoing (channels)

Product 0000-0156 0.0 to current version

- 210731 me new doc
- 210801 me last update

Table of contents:

- [Outgoing \(channels\)](#)
 - [Outgoing channels overview](#)
 - [REST outgoing definition](#)

17.1 Outgoing channels overview

An outgoing channel is a **output endpoint** from a service. It will act as an endpoint usable by a service to access an external system. They will be named as short *OUTGOING* or *OUTCONNS*.

Outgoings can use multiple standard destinations, SAP queues (ex AMQPz IBM), databases, mail and so on.

Outconns are typically invoked (by a service) using attributes from self.out, e.g. self.out.rest, self.out.amqp, self.out.sap and so on, maintaining a connection pool internally when needed so that services can just focus on the invocation part.

17.2 REST outgoing definition

For an **outgoing**, the following parameters must be provided:

- Name
- Host
- URL path
- Data format
- Service
- Security definition

(NOTE: it is important to retain the default HEAD ping method, because it will be used to check the endpoint availability)

Name is the ARCLST name of the channel.

URL path is the address of channel endpoint. This is part of ARCLST route, ie `ARCLST_path.../URL_path`.

Data format is the format of data that will be exchanged through this channel. Usual (for REST channels at least) is to specify here *JSON*.

Service is the name of the service that will be called when channel is invoked.

Security represents the security domain that will be applied to this channel.

Other parameters could also be specified here, for example if there are supplementary parameters (like those with ? after the route), header info (for out channels) and so on.

18 API Security

Table of contents:

- [API Security](#)
 - [Security overview](#)
 - [Define basic security rules](#)

18.1 Security overview

Mainly security is used to secure channels. As long as a service can interact with external world thru channels, this is clearly enough for all normal operations.

System allow for multiple security models, types and protocols. There ca be active more security rules, each one applicable as needed in various circumstances.

18.2 Define basic security rules

By **basic security** is understood a rule based on requesting explicitly an user and a password.

Basic security rules can be defined from administration console, *Security* menu, *Basic auth* entry. A security rule means:

- a name for the rule
- an username
- a domain in which rule is applicable (think domain as a kind of grouping more rules in a set usable for a purpose, for example channels); thid approach allows for many to many relationships between security rules and channels or other objects

Password will be generated automatically as uuid4 (guid) and This can be modified latter.
